1. UX Problem Definition and Vibe Coding Approach

Our project tackles the challenge of everyday navigation in Bergen, aiming to create a faster and more intuitive way to get from A to B. Existing apps such as Skyss Reise and Google Maps offer many features, but their interfaces often feel cluttered or unintuitive. We saw an opportunity to design a navigation tool that focuses on simplicity rather than complexity.

Inspired by the early concept “here2there” by X user @jazzychad (Figure 1), we explored the idea of a circular navigation wheel with draggable nodes. The basic interaction, dragging from a start to an endpoint, felt natural and reduced the number of choices users usually face. This became the foundation of our design philosophy: a clean, minimal interface that supports engaging interaction without unnecessary features.

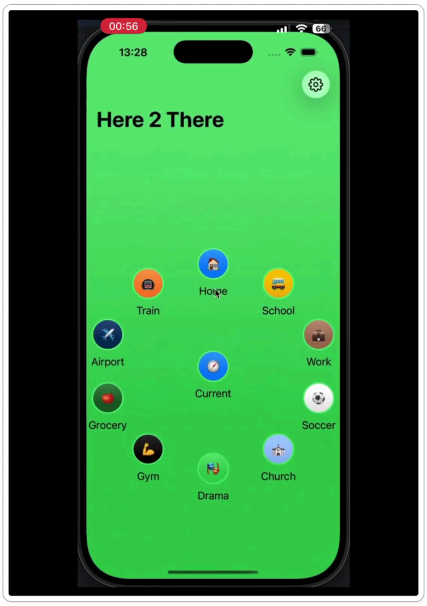

Figure 1: Screenshot of Here2There. CC: @jazzychad at X.com

Early in the process, we committed to the circular interface metaphor, which supports a more tactile and “felt” interaction aligned with vibe coding. Vibe coding allowed us to focus not just on functionality, but also on flow, clarity, and emotional ease. We

could quickly test layout ideas, visualize concepts, and decide what to keep or discard.

During the exploration phase, we produced many wireframes and interaction sketches. Here, the AI-assisted tool Figma Make proved quite useful. It enabled everyone, from designers to developers and researchers, to participate equally in rapid idea generation. High-quality prototypes could be created in minutes, letting us test variations of the navigation wheel quickly and refine our direction.

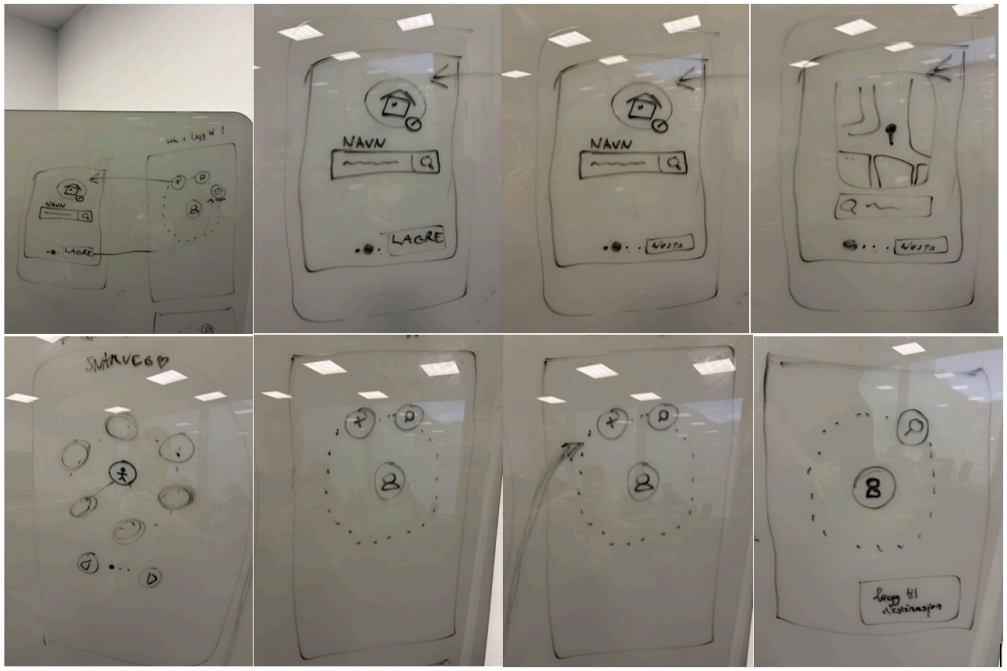

Figure 2: Early app core functionality design exploration, which we fed into Figma Make.

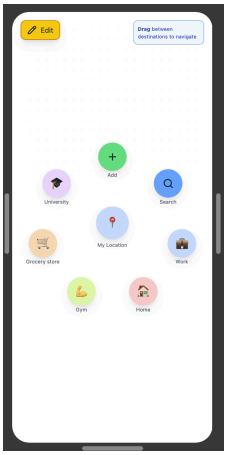

Figure 3: The Figma Make prototype of the wheel, born from early sketches (see figure 2).

We also set up a shared FigJam workspace with boards for prompts, wireframes, research insights, competitor analysis, and MoSCoW prioritization. This helped us stay aligned with user needs while expanding on each other's ideas.

Figure 4: Screenshot from FigJam board of a User Journey map. For Personas and Empathy maps, we did the exercise first as a team, and then we let ChatGPT do it, so we could compare outputs.

By combining vibe coding, rapid prototyping, and collaborative AI tools, we developed not only how the prototype works, but how it feels. This established a strong emotional connection to the project, and a good experiential foundation for the rest of the design and development process.

2. Conceptual Prototype Description

Snarveg is built around one central design metaphor: **navigation as a wheel**. Instead of relying on long menus, form fields, or detailed map views, the prototype focuses on the simplest possible interaction—showing where you are and where you want to go. The wheel offers a tactile and intuitive way to express movement through a drag-and-drop gesture, aligning with our overall aim of reducing cognitive complexity.

2.1 A personal weel of destinations

The prototype visualizes a circular wheel composed of nodes. The central node represents the user's current position, while the surrounding nodes display the user’s personal destinations. These nodes can be fully customized—users may change color, icon, label, and coordinates—allowing the interface to adapt to individual routines and preferences. Each node represents a meaningful place such as home, school, work, or any custom location the user chooses to add. This spatial configuration provides immediate orientation without overwhelming the user with excess information.

Users can easily add new destinations through a “+” node, and the wheel automatically adjusts to maintain a balanced layout. An **edit mode** enables users to reorganize or remove nodes, with the wheel dynamically adapting to the changes.

2.2 Core features

Circular Navigation Wheel: The central UI element, representing the users personal geography in a visually minimal and cognitively light manner.

Node-Based Destinations: Each destination is represented through color, iconography, and a short label, rather than text-heavy lists or traditional address inputs.

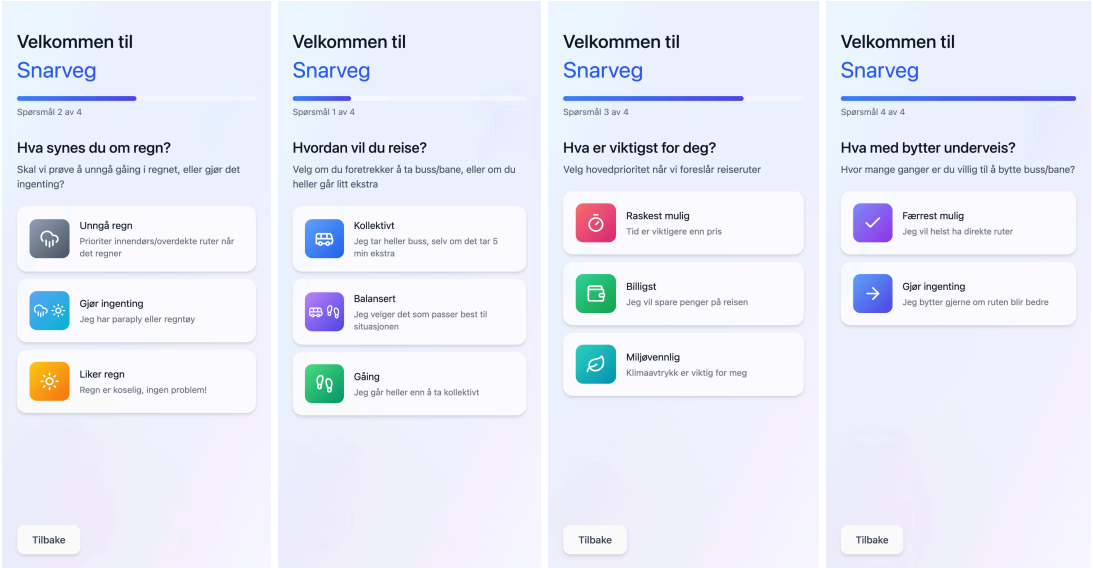

Drag-and-Drop function: Users select a route by dragging from one node to another. This gesture communicates intent directly and fosters a more embodied and intuitive interaction.

Ticket Indicator and Purchase Flow: A small ticket icon in the corner displays a green or red indicator showing whether the user currently holds a valid ticket. Users can purchase tickets either before or after selecting a route, and recommended tickets are surfaced based on the chosen journey.

2.3 Interaction flow

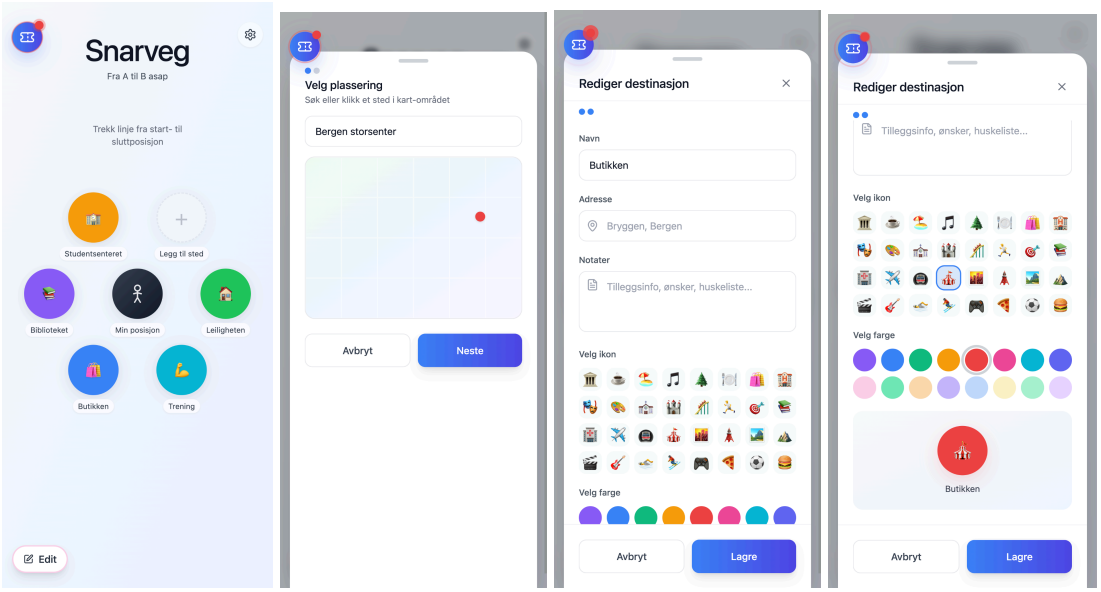

1. **Onboarding**

   Users set initial preferences - do they want to avoid rain as much as possible, are they environmentally conscious, are they willing to change modes of transport to get there faster? These preferences can later be modified in the settings

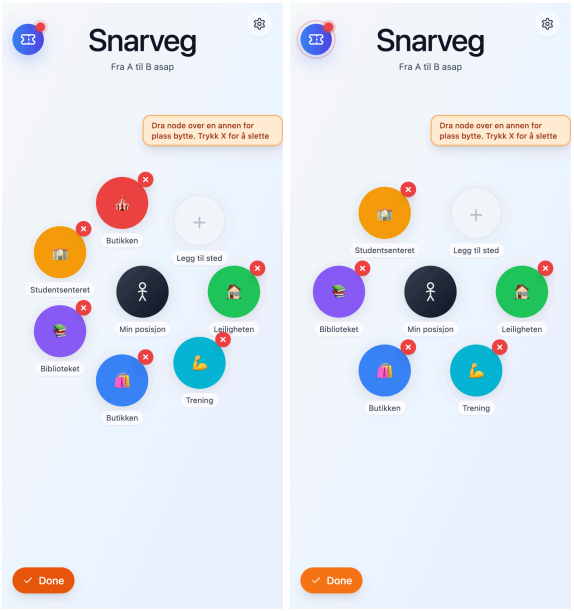

2. **Home Screen – The Wheel**

   The user is presented with the navigation wheel displaying their current position and personal destinations. It's also possible to add nodes.

3. **Edit Mode:** A dedicated mode where users can reorganize nodes, delete destinations, or adjust details without disturbing the core navigation experience.

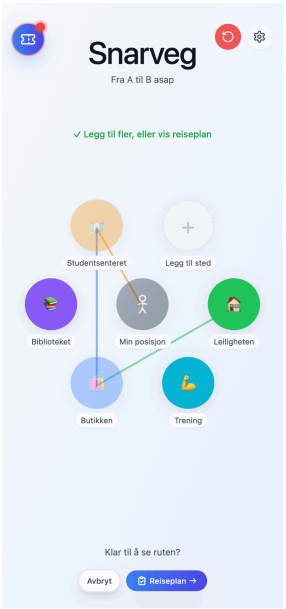

4. **Selecting a start node**

   The user either uses their current location or selects a destination as the starting point.

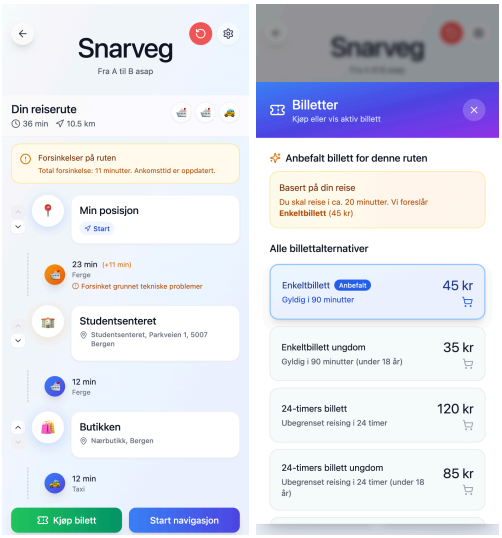

5. **Drag-and-Drop Routing**

   The user drags from the start node to the target destination. Additional destinations can be added if needed, and a connection line is drawn

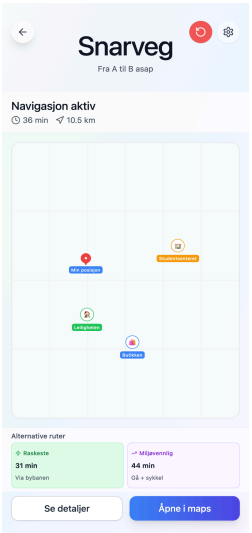

6. **Route Overview**

   The user gets a clear summary of the selected route, including transport and ticket purchases, with ticket suggestions for the route. It's also possible to change the order in the route.

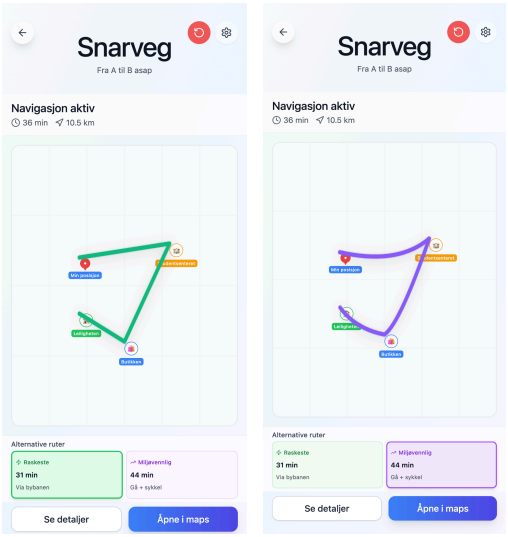

7. **Navigation Active**

   After the user selects their destinations and clicks the “Start Navigation” button, the travel route is visualized on a map. The intention is that clicking directly on the map will open the route in a mapping application, or alternatively through the “Open in Maps” button. The goal is to integrate the solution with existing map visualization tools.

8. **Route Preferences**

   Based on the settings selected during onboarding, the user is given the opportunity to visualize routes according to their own preferences. In this example, the user has chosen to see both the most environmentally friendly route and the fastest route. Both routes are clearly displayed on the map, in relation to the selected destinations.

2.4 Design Emphasis: Wheel, drag-and-drop and simplicity

Every part of the interface is built around the principles of simplicity and clear visual structure. The simple navigation wheel and drag-and-drop functionality creates a direct and intuitive interaction, and the overall minimalist design ensures that the user can focus on the most important task: getting from A to B quickly and effortlessly. This simplicity reduces the user's cognitive load, aligning with Norman´s (2014) view that well-structured interfaces can make even complex systems feel easy to use.

2.5 Influence of vibe coding:

Vibe coding played a central role in shaping these elements. Beyond specifying technical details, functions, and visual design, we used prompts that emphasised atmosphere, clarity, and intuitive flow - such as "the drag-and-drop interaction should feel simple and intuitive to use" or "the gesture should feel smooth, really user

friendly and playful.” This approach enabled us to generate early prototypes with a coherent mood and interaction flow, ensuring that the experience felt simple, consistent, and pleasant to use.

3. Design and Development Process

Our design and development process followed an iterative and collaborative workflow shaped by vibe coding and AI-assisted prototyping. Instead of defining a fixed structure at the beginning, we allowed the prototype to evolve through continuous exploration, experimentation, and emotional evaluation. This approach enabled us to refine both the concept and interaction flow as we progressed.

- **Figma Make** for rapid, AI-generated UI concepts
- **Figma** for wireframes, user flows, and design boards
- **React** for building the functional prototype
- **GitHub** for version control and collaboration
- **Cursor/ChatGPT** for vibe coding and code generation
- **ChatGPT** for Cursor prompt tuning and analysis of qualitative research data

4. Evaluation and Validation

We began user testing by discussing our concept internally and then used ChatGPT to help create an interview guide focused on navigation habits in Bergen. With this AI-assisted outline, we conducted six interviews with participants aged 20–30. After collecting our notes, we carried out two activities to better understand our users: creating empathy maps and asking ChatGPT to generate its own based on anonymised notes. The AI surfaced insights we hadn’t initially considered. We then developed personas ourselves while comparing them to AI-generated versions, ultimately preferring the manual approach because it kept us more connected to real users. Throughout development, AI sped up our workflow by turning ideas into quick Figma Make mockups and, with Cursor and ChatGPT-tailored prompts, into implemented features within minutes.

5. Reflection and Future Work

5.1 Contribution

Oline

As the team's front-end developer, my main role was to set up the project framework and translate our design into functional code. I implemented the navigation wheel, drag-and-drop routing, node management, and the edit mode and ensured that the prototype worked across devices. I worked with AI tools such as Figma Make in the design process, and Cursor Pro and ChatGPT in the development process. Rather than relying on a single prompt, I refined prompts step by step by testing the output, identifying issues, and specifying targeted adjustments.

This process taught me how crucial precise prompts and clear descriptions of design intentions are for achieving the desired result. Although AI tools are highly capable, they still require human judgment, debugging, and design awareness. Overall, the project strengthened my frontend skills and my ability to collaborate efficiently with AI tools.

Ole

As the group’s lead UX researcher, my goal was to gather an empirical foundation for the project. We felt strongly that the wheel-interaction could be useful, but we needed proof.

My contributions to the project have been preparing and doing user interviews to gather data, as well as setting up research exercises like empathy mapping and the MoSCoW method to turn data into insight for the project. Along with this, I have been testing how a language model like ChatGPT could assist us in this process, and have made a lot of interesting discoveries along the way.

Sol:

In this project, I took the lead in the design phase while still collaborating closely with the rest of the team throughout all stages of the process. My primary responsibility was to translate our UX research into concrete UX design solutions. This involved developing wireframes, creating interactive prototypes, and iterating on these designs based on testing and feedback. We worked mainly in Figma Make, supplemented by traditional whiteboard sketching during team sessions, to explore ideas and refine the user flow. The design phase was highly collaborative, requiring continuous communication with our developer, Oline, to ensure alignment between design intentions and the technical implementation. Through regular feedback loops and design sparring, we ensured that the evolving product maintained both usability and feasibility throughout development.
